LPC 2015

Using seccomp to limit the kernel attack surface

Outline

1 Introductions

- 2 Introduction and history
- 3 Seccomp filtering and BPF
- 4 Constructing seccomp filters
- 5 BPF programs
- 6 Further details on seccomp filters
- 7 Applications, tools, and further information

Who am I?

- Maintainer of Linux man-pages (since 2004)
 - Documents kernel-user-space + C library APIs
 - ~1000 manual pages
 - http://www.kernel.org/doc/man-pages/
- API review, testing, and documentation
 - API design and design review
 - Lots of testing, lots of bug reports, a few kernel patches
- "Day job": programmer, trainer, writer

1 Introductions

2 Introduction and history

- 3 Seccomp filtering and BPF
- 4 Constructing seccomp filters
- 5 BPF programs
- 6 Further details on seccomp filters
- 7 Applications, tools, and further information

Goals

- History of seccomp
- Basics of seccomp operation
- Creating and installing BPF filters (AKA "seccomp2")
 - Mostly: look at hand-coded BPF filter programs, to gain fundamental understanding of how seccomp works
 - Briefly note some productivity aids for coding BPF programs

- Mechanism to restrict system calls that a process may make
 - Reduces attack surface of kernel
 - A key component for building application sandboxes
- First version in Linux 2.6.12 (2005)
 - Filtering enabled via /proc/PID/seccomp
 - Writing "1" to file places process (irreversibly) in "strict" seccomp mode
 - Need CONFIG_SECCOMP

Initially, just one filtering mode ("strict")

- Only permitted system calls are read(), write(), _exit(), and sigreturn()
 - Note: *open()* not included (must open files before entering strict mode)
 - *sigreturn()* allows for signal handlers
- Other system calls \Rightarrow SIGKILL
- Designed to sandbox compute-bound programs that deal with untrusted byte code
 - Code perhaps exchanged via pre-created pipe or socket

Linux 2.6.23 (2007):

- /proc/PID/seccomp interface replaced by *prctl()* operations
- prctl(PR_SET_SECCOMP, arg) modifies caller's seccomp mode
 - SECCOMP_MODE_STRICT: limit syscalls as before
- prctl(PR_GET_SECCOMP) returns seccomp mode:
 - $0 \Rightarrow$ process is not in seccomp mode
 - Otherwise?
 - SIGKILL (!)
 - prctl() is not a permitted system call in "strict" mode
 - Who says kernel developers don't have a sense of humor?

- Linux 3.5 (2012) adds "filter" mode (AKA "seccomp2")
 - prctl(PR_SET_SECCOMP, SECCOMP_MODE_FILTER, ...)
 - Can control which system calls are permitted,
 - Control based on system call number and argument values
 - Choice is controlled by user-defined filter-a BPF "program"
 - Berkeley Packet Filter (later)
 - Requires CONFIG_SECCOMP_FILTER
 - By now used in a range of tools
 - E.g., Chrome browser, OpenSSH, *vsftpd*, Firefox OS, Docker

• Linux 3.8 (2013):

2

- The joke is getting old...
- New /proc/PID/status Seccomp field exposes process seccomp mode (as a number)

0 // SECCOMP_MODE_DISABLED

- 1 // SECCOMP_MODE_STRICT
 - // SECCOMP_MODE_FILTER
- Process can, without fear, read from this file to discover its own seccomp mode
 - But, must have previously obtained a file descriptor...

- Linux 3.17 (2014):
 - seccomp() system call added
 - (Rather than further multiplexing of *prctl()*)
 - Provides superset of *prctl(2)* functionality
 - Can synchronize all threads to same filter tree
 - Useful, e.g., if some threads created by start-up code before application has a chance to install filter(s)

1 Introductions

2 Introduction and history

3 Seccomp filtering and BPF

- 4 Constructing seccomp filters
- 5 BPF programs
- 6 Further details on seccomp filters
- 7 Applications, tools, and further information

Seccomp filtering and BPF

- Seccomp filtering available since Linux 3.5
- Allows filtering based on system call number and argument (register) values
 - Pointers are **not** dereferenced
- Filters expressed using BPF (Berkeley Packet Filter) syntax
- Filters installed using seccomp() or prctl()
 - Construct and install BPF filter
 - exec() new program or invoke function inside dynamically loaded shared library (plug-in)
- Once installed, every syscall triggers execution of filter
 - Installed filters can't be removed
 - Filter == declaration that we don't trust subsequently executed code

BPF origins

- BPF originally devised (in 1992) for *tcpdump*
 - Monitoring tool to display packets passing over network
 - http://www.tcpdump.org/papers/bpf-usenix93.pdf
- $\bullet\,$ Volume of network traffic is enormous $\Rightarrow\,$ must filter for packets of interest
- BPF allows in-kernel selection of packets
 - Filtering based on fields in packet header
- Filtering in kernel more efficient than filtering in user space
 - Unwanted packet are discarded early
 - \Rightarrow Avoids passing **every** packet over kernel-user-space boundary

BPF virtual machine

- BPF defines a **virtual machine** (VM) that can be implemented inside kernel
- VM characteristics:
 - Simple instruction set
 - Small set of instructions
 - All instructions are same size
 - Implementation is simple and fast
 - Only branch-forward instructions
 - Programs are directed acyclic graphs (DAGs)
 - Easy to verify validity/safety of programs
 - Program completion is guaranteed (DAGs)
 - $\bullet~$ Simple instruction set \Rightarrow can verify opcodes and arguments
 - Can detect dead code
 - Can verify that program completes via a "return" instruction
 - BPF filter programs are limited to 4096 instructions

Generalizing BPF

- BPF originally designed to work with network packet headers
- Seccomp 2 developers realized BPF could be generalized to solve different problem: filtering of system calls
 - Same basic task: test-and-branch processing based on content of a small set of memory locations
- Further generalization ("extended BPF") is ongoing
 - Linux 3.18: adding filters to kernel tracepoints
 - Linux 3.19: adding filters to raw sockets
 - In progress (July 2015): filtering of perf events

1 Introductions

- 2 Introduction and history
- 3 Seccomp filtering and BPF

4 Constructing seccomp filters

- 5 BPF programs
- 6 Further details on seccomp filters
- 7 Applications, tools, and further information

Basic features of BPF virtual machine

- Accumulator register
- Data area (data to be operated on)
 - In seccomp context: data area describes system call
- Implicit program counter
 - (Recall: all instructions are same size)
- Instructions contained in structure of this form:

```
struct sock_filter { /* Filter block */
__u16 code; /* Filter code (opcode)*/
__u8 jt; /* Jump true */
__u8 jf; /* Jump false */
__u32 k; /* Generic multiuse field */
};
```

• See <linux/filter.h> and <linux/bpf_common.h>

BPF instruction set

Instruction set includes:

- Load instructions
- Store instructions
- Jump instructions
- Arithmetic/logic instructions
 - ADD, SUB, MUL, DIV, MOD, NEG
 - OR, AND, XOR, LSH, RSH
- Return instructions
 - Terminate filter processing
 - Report a status telling kernel what to do with syscall

BPF jump instructions

- Conditional and unconditional jump instructions provided
- Conditional jump instructions consist of
 - Opcode specifying condition to be tested
 - Value to test against
 - Two jump targets
 - jt: target if condition is true
 - jf: target if condition is false
- Conditional jump instructions:
 - JEQ: jump if equal
 - JGT: jump if greater
 - JGE: jump if greater or equal
 - JSET: bit-wise AND + jump if nonzero result

BPF jump instructions

- Targets are expressed as relative offsets in instruction list
 - 0 == no jump (execute next instruction)
 - jt and jf are 8 bits $\Rightarrow 255$ maximum offset for conditional jumps
- Unconditional JA ("jump always") uses k as offset, allowing much larger jumps

Seccomp BPF data area

- Seccomp provides data describing syscall to filter program
 Buffer is read-only
- Format (expressed as C struct):

<pre>struct seccomp_data {</pre>	
int nr;	/* System call number */
u32 arch;	/* AUDIT_ARCH_* value */
u64 instruction_pointer;	/* CPU IP */
u64 args[6];	/* System call arguments */
};	-

- nr: system call number (architecture-dependent)
- arch: identifies architecture
 - Constants defined in <linux/audit.h>
 - AUDIT_ARCH_X86_64, AUDIT_ARCH_I386, AUDIT_ARCH_ARM, etc.
- instruction_pointer: CPU instruction pointer
- args: system call arguments
 - System calls have maximum of six arguments

man7.org

- Obviously, one can code BPF instructions numerically by hand
- But, header files define symbolic constants and convenience macros (BPF_STMT(), BPF_JUMP()) to ease the task

• (Macros just plug values together to form structure)

Building BPF instructions: examples

• Load architecture number into accumulator

- Opcode here is constructed by ORing three values together:
 - BPF_LD: load
 - BPF_W: operand size is a word
 - BPF_ABS: address mode specifying that source of load is data area (containing system call data)
 - See <linux/bpf_common.h> for definitions of opcode constants
- offsetof() generates offset of desired field in data area

Building BPF instructions: examples

Test value in accumulator

```
BPF_JUMP(BPF_JMP | BPF_JEQ | BPF_K,
AUDIT_ARCH_X86_64, 1, 0)
```

- BPF_JMP | BPF_JEQ: jump with test on equality
- BPF_K: value to test against is in generic multiuse field (k)
- k contains value AUDIT_ARCH_X86_64
- jt value is 1, meaning skip one instruction if test is true
- jf value is 0, meaning skip zero instructions if test is false
 I.e., continue execution at following instruction
- Return value that causes kernel to kill process with SIGSYS

BPF_STMT(BPF_RET | BPF_K, SECCOMP_RET_KILL)

Checking the architecture

- Checking architecture value should be first step in any BPF program
- Architecture may support multiple system call conventions
 - E.g. x86 hardware supports x86-64 and i386
 - System call numbers may differ or overlap

Filter return value

- Once a filter is installed, each system call is tested against filter
- Seccomp filter must return a value to kernel indicating whether system call is permitted
 - Otherwise EINVAL when attempting to install filter
- Return value is 32 bits, in two parts:
 - Most significant 16 bits (SECCOMP_RET_ACTION mask) specify an action to kernel
 - Least significant 16 bits (SECCOMP_RET_DATA mask) specify "data" for return value

Filter return action

Filter return action component is one of

- SECCOMP_RET_ALLOW: system call is executed
- SECCOMP_RET_KILL: process is immediately terminated
 - Terminated as though process had been killed with SIGSYS
- SECCOMP_RET_ERRNO: return an error from system call
 - System call is not executed
 - Value in SECCOMP_RET_DATA is returned in *errno*
- SECCOMP_RET_TRACE: attempt to notify *ptrace()* tracer
 - Gives tracing process a chance to assume control
 - See seccomp(2)
- SECCOMP_RET_TRAP: process is sent SIGSYS signal
 - Can catch this signal; see seccomp(2) for more details

1 Introductions

- 2 Introduction and history
- 3 Seccomp filtering and BPF
- 4 Constructing seccomp filters

5 BPF programs

- 6 Further details on seccomp filters
- 7 Applications, tools, and further information

Installing a BPF program

- A process installs a filter for itself using one of:
 - seccomp(SECCOMP_SET_MODE_FILTER, flags, &fprog)
 - Only since Linux 3.17
 - prctl(PR_SET_SECCOMP, SECCOMP_MODE_FILTER, &fprog)
- & fprog is a pointer to a BPF program:

Installing a BPF program

To install a filter, one of the following must be true:

- Caller is privileged (CAP_SYS_ADMIN)
- Caller has to set the no_new_privs process attribute:

```
prctl(PR_SET_NO_NEW_PRIVS, 1);
```

- Causes set-UID/set-GID bit / file capabilities to be ignored on subsequent execve() calls
 - Once set, no_new_privs can't be unset
- Prevents possibility of attacker starting privileged program and manipulating it to misbehave using a seccomp filter

Example: seccomp/seccomp_deny_open.c

```
1 int main(int argc, char **argv) {
2     prctl(PR_SET_NO_NEW_PRIVS, 1, 0, 0, 0);
3
4     install_filter();
5
6     open("/tmp/a", O_RDONLY, 0666);
7
8     printf(" We shouldn't see this message\n");
9     exit(EXIT_SUCCESS);
10 }
```

Program installs a filter that prevents *open()* being called, and then calls *open()*

- Set no_new_privs bit
- Install seccomp filter
- Call open()

Example: seccomp/seccomp_deny_open.c

```
1 static void install_filter(void) {
2 struct sock_filter filter[] = {
3 BPF_STMT(BPF_LD | BPF_W | BPF_ABS,
4 (offsetof(struct seccomp_data, arch))),
5 BPF_JUMP(BPF_JMP | BPF_JEQ | BPF_K,
6 AUDIT_ARCH_X86_64, 1, 0),
7 BPF_STMT(BPF_RET | BPF_K, SECCOMP_RET_KILL),
8 ...
```

- Define and initialize array (of structs) containing BPF filter program
- Load architecture into accumulator
- Test if architecture value matches AUDIT_ARCH_X86_64
 - True: jump forward one instruction (i.e., skip next instruction)
 - False: skip no instructions

• Kill process on architecture mismatch

Example: seccomp/seccomp_deny_open.c

```
1 BPF_STMT(BPF_LD | BPF_W | BPF_ABS,
2 (offsetof(struct seccomp_data, nr))),
3 
4 BPF_JUMP(BPF_JMP | BPF_JEQ | BPF_K, __NR_open,
5 1, 0),
6 BPF_STMT(BPF_RET | BPF_K, SECCOMP_RET_ALLOW),
7 
8 BPF_STMT(BPF_RET | BPF_K, SECCOMP_RET_KILL)
9 };
```

- Remainder of filter program
- Load system call number into accumulator
- Test if system call number matches __NR_open
 - True: advance one instruction \Rightarrow kill process
 - False: advance 0 instructions \Rightarrow allow system call

Example: seccomp/seccomp_deny_open.c

- Construct argument for seccomp()
- Install filter

Example: seccomp/seccomp_deny_open.c

Upon running the program, we see:

```
$ ./seccomp_deny_open
Bad system call # Message printed by shell
$ echo $? # Display exit status of last command
159
```

- "Bad system call" indicates process was killed by SIGSYS
- Exit status of 159 (== 128 + 31) also indicates termination as though killed by SIGSYS
 - Exit status of process killed by signal is 128 + signum
 - SIGSYS is signal number 31 on this architecture

- A more sophisticated example
- Filter based on *flags* argument of *open()*
 - O_CREAT specified \Rightarrow kill process
 - O_WRONLY or O_RDWR specified ⇒ cause open() to fail with ENOTSUP error

```
struct sock_filter filter[] = {
  BPF_STMT(BPF_LD | BPF_W | BPF_ABS,
        (offsetof(struct seccomp_data, arch))),
  BPF_JUMP(BPF_JMP | BPF_JEQ | BPF_K,
        AUDIT_ARCH_X86_64, 1, 0),
  BPF_STMT(BPF_RET | BPF_K, SECCOMP_RET_KILL),
  BPF_STMT(BPF_LD | BPF_W | BPF_ABS,
        (offsetof(struct seccomp_data, nr))),
  BPF_JUMP(BPF_JMP | BPF_JEQ | BPF_K, __NR_open, 1, 0),
  BPF_STMT(BPF_RET | BPF_K, SECCOMP_RET_ALLOW),
```

- Load architecture and test for expected value
- Load system call number
- Test if system call number is __NR_open
 - True: skip next instruction
 - False: skip 0 instructions \Rightarrow permit all other syscalls

- Load second argument of open() (flags)
- Test if O_CREAT bit is set in *flags*
 - True: skip 0 instructions \Rightarrow kill process
 - False: skip 1 instruction

• Test if O_WRONLY or O_RDWR are set in *flags*

- True: cause open() to fail with ENOTSUP error in errno
- False: allow open() to proceed

```
int main(int argc, char **argv) {
    prctl(PR_SET_NO_NEW_PRIVS, 1, 0, 0, 0);
    install filter();
    if (open("/tmp/a", O_RDONLY) == -1)
        perror("open1");
    if (open("/tmp/a", O_WRONLY) == -1)
        perror("open2");
    if (open("/tmp/a", O_RDWR) == -1)
        perror("open3");
    if (open("/tmp/a", O_CREAT | O_RDWR, 0600) == -1)
        perror("open4");
    exit(EXIT SUCCESS);
}
```

• Test open() calls with various flags

```
$ ./seccomp_control_open
open2: Operation not supported
open3: Operation not supported
Bad system call
$ echo $?
159
```

- First open() succeeded
- Second and third open() calls failed
 - Kernel produced ENOTSUP error for call
- Fourth open() call caused process to be killed

- 1 Introductions
- 2 Introduction and history
- 3 Seccomp filtering and BPF
- 4 Constructing seccomp filters
- 5 BPF programs
- 6 Further details on seccomp filters
- 7 Applications, tools, and further information

Installing multiple filters

- If existing filters permit *prctl()* or *seccomp()*, further filters can be installed
- All filters are always executed, in reverse order of registration
- Each filter yields a return value
- Value returned to kernel is first seen action of highest priority (along with accompanying data)
 - SECCOMP_RET_KILL (highest priority)

SECCOMP_RET_ALLOW (lowest priority)

- SECCOMP_RET_TRAP
- SECCOMP_RET_ERRNO
- SECCOMP_RET_TRACE

fork() and execve() semantics

- If seccomp filters permit *fork()* or *clone()*, then child inherits parents filters
- If seccomp filters permit execve(), then filters are preserved across execve()

Cost of filtering, construction of filters

- Installed BPF filter(s) are executed for every system call
 - \Rightarrow there's a performance cost
- Example on x86-64:
 - Use our "deny open" seccomp filter
 - Requires 6 BPF instructions / permitted syscall
 - Call getppid() repeatedly (one of cheapest syscalls)
 - +25% execution time
 - (Looks relatively high because *getppid()* is a cheap syscall)
- Obviously, order of filtering rules can affect performance
- Construct filters so that most common cases yield shortest execution paths
- If handling many different system calls, binary chop techniques can give O(logN) performance

- 1 Introductions
- 2 Introduction and history
- 3 Seccomp filtering and BPF
- 4 Constructing seccomp filters
- 5 BPF programs
- 6 Further details on seccomp filters
- 7 Applications, tools, and further information

Applications

Possible applications:

- Building sandboxed environments
 - Whitelisting usually safer than blacklisting
 - Default treatment: block all system calls
 - Then allow only a limited set of syscall / argument combinations
 - Various examples mentioned earlier
- Failure-mode testing
 - Place application in environment where unusual / unexpected failures occur
 - Blacklist certain syscalls / argument combinations to generate failures

Tools: *libseccomp*

- High-level API for kernel creating seccomp filters
 - https://github.com/seccomp/libseccomp
 - Initial release: 2012
- Simplifies various aspects of building filters
 - Eliminates tedious/error-prone tasks such as changing branch instruction counts when instructions are inserted
 - Abstract architecture-dependent details out of filter creation
 - Can output generated code in binary (for seccomp filtering) or human-readable form ("pseudofilter code")
 - Don't have full control of generated code, but can give hints about which system calls to prioritize in generated code
- http://lwn.net/Articles/494252/

 ${\ensuremath{\, \bullet }}$ Fully documented with man pages that contain examples (!)

Other tools

- *bpfc* (BPF compiler)
 - Compiles assembler-like BPF programs to byte code
 - Part of netsniff-ng project (http://netsniff-ng.org/)
- LLVM has a BPF back end (merged Jan 2015)
 - Compiles subset of C to BPF
 - C dialect; does not provide: loops, global variables, FP numbers, vararg functions, passing structs as args...
 - Examples in kernel source: samples/bpf/*_kern.c
- In-kernel JIT (just-in-time) compiler
 - Compiles BPF binary to native machine code at load time
 - Execution speed up of 2x to 3x (or better, in some cases)
 - Disabled by default; enable by writing "1" to /proc/sys/net/core/bpf_jit_enable
 - See *bpf(2)* man page

- Kernel source files: Documentation/prctl/seccomp_filter.txt, Documentation/networking/filter.txt
- http://outflux.net/teach-seccomp/
 - Shows handy trick for discovering which of an application's system calls don't pass filtering
- seccomp(2) man page
- "Seccomp sandboxes and memcached example"
 - $\bullet \quad blog.viraptor.info/post/seccomp-sandboxes-and-memcached-example-part-1\\$
 - blog.viraptor.info/post/seccomp-sandboxes-and-memcached-example-part-2
