6.6	Exercises	6-24

Run-time symbol resolution

 Suppose main program and shared library both define a function xyz(), and another function inside library calls xyz()libfoo.so

```
xyz(){
  printf("main-xyz\n");
                                        printf("foo-xyz\n");
main() {
                                       func() {
                                         xyz();
```

- To which symbol does reference to xyz() resolve?
- The results may seem a little surprising:

```
$ cd shlibs/sym_res_demo
$ cc -g -c -fPIC -Wall foo.c
$ cc -g -shared -o libfoo.so foo.o
$ cc -g -o prog prog.c libfoo.so
$ LD_LIBRARY_PATH=. ./prog
```

Definition in main program overrides version in library!

Symbol interposition

- When a symbol definition inside an object is overridden by an outside definition, we say symbol has been interposed
 - Interposition can occur for both functions and variables
- Behavior shown 6-4 has a good historical reason...
- Shared libraries are designed to mirror traditional static library semantics:
 - Definition of global symbol in main program overrides version in library
 - Global symbol appears in multiple libraries?
 - reference is resolved to first definition when scanning libraries in left-to-right order as specified in static link command line
- Interposition behavior made transition from static to shared libraries easier

Shared Libraries on Linux

Symbol Interposition and Library Load Order

6-5 §6.1

Interposition vs libraries as self-contained subsystems

- Symbol interposition semantics conflict with model of shared library as a self-contained subsystem
 - Shared library can't guarantee that reference to its own global symbols will bind to those symbols at run time
 - Properties of shared library may change when it is aggregated into larger system
- Can sometimes be desirable to force symbol references within a shared library to resolve to library's own symbols
 - I.e., prevent interposition by outside symbol definition

Forcing global symbol references to resolve inside library

• -Bsymbolic linker option causes references to global symbols within shared library to resolve to library's own symbols

```
$ cd shlibs/sym_res_demo
$ cc -g -c -fPIC -Wall foo.c
$ cc -g -shared <u>-Wl,-Bsymbolic</u> -o libfoo.so foo.o
$ cc -g -o prog prog.c libfoo.so
$ LD_LIBRARY_PATH=. ./prog
foo-xyz
```

- Adds ELF DF SYMBOLIC flag in .dynamic section of object
 - Or DT SYMBOLIC tag in older binaries
- To see if object was built with this option, use either of:

```
objdump -p libfoo.so | grep SYMBOLIC readelf -d libfoo.so | grep SYMBOLIC
```

- DF SYMBOLIC flag in a library affects only the library itself (not dependencies of the library)
- More extensive example: shlibs/demo Bsymbolic

Symbol Interposition and Library Load Order

6-7 §6.1

Forcing global symbol references to resolve inside library

- Problem: −Bsymbolic affects all symbols in shared library ②
 - And there are other problems...

©2025 M. Kerrisk

- Preferable to control "local reference binds to local definition" behavior on a per-symbol basis
 - Other techniques (described later) allow this ☺

Symbol resolution and library load order

- Main program has three dynamic dependencies
- Some libraries on which main has dependencies in turn have dependencies
 - **Note**: main program has no direct dependencies other than libx1.so, liby1.so, and libz1.so
 - Likewise, libz1.so has no direct dependency on libz3.so

Symbol resolution and library load order

```
..main_prog...
libx1.so
                 liby1.so
                                      libz1.so
                     | abc(){...}
                                            call abc()
libx2.so
                 liby2.so
                                      libz2.so
                   xyz(){...}
  abc(){...}
  xyz()\{\ldots\}
                                      libz3.so
                                        xyz()\{\ldots\}
```

- libx2.so and liby1.so both define public function abc()
- When abc() is called from inside libz1.so, which instance of *abc()* is invoked?
 - Call to abc() resolves to definition in liby1.so

Shared Libraries on Linux

©2025 M. Kerrisk

Symbol Interposition and Library Load Order

6-11 §6.2

Symbol resolution and library load order

```
..main_prog.....
libx1.so
                 liby1.so
                                     libz1.so
                    | abc(){...}
                                            call abc()
libx2.so
                 liby2.so
                                     libz2.so
  abc(){...}
                   xyz()\{\ldots\}
  xyz(){...}
                                     libz3.so
                                       xyz()\{\ldots\}
```

- Dependent libraries are added in breadth-first order
 - Immediate dependencies of main program are loaded first
 - Then dependencies of those dependencies, and so on
 - Libraries that are already loaded are skipped (but are reference) counted)
- Symbols are resolved by searching libraries in load order

Symbol resolution and library load order

- A quiz...
- libx2.so, liby2.so, and libz3.so all define public function xyz()
- When xyz() is called from inside libz1.so, which instance of xyz() is invoked?
 - Call to xyz() resolves to definition in libx2.so

6-13 §6.2

6 Symbol Interposition and Library Load Order	6-1
6.1 Symbol resolution and symbol interposition	6-3
6.2 Symbol resolution and library load order	6-9
6.3 Link-map lists (namespaces)	6-14
6.4 The global look-up scope	6-16
6.5 LD_DEBUG: tracing the dynamic linker	6-18
6.6 Exercises	6-24

Link-map lists ("namespaces")

- The set of all objects that have been loaded by application is recorded in a **link-map list** (AKA "namespace")
 - Doubly linked list that is arranged in library load order
 - Main program is at front of link map
 - See definition of struct link_map in <link.h>
 - dl_iterate_phdr(3) can be used to iterate through list
 - Example program: shlibs/dl_iterate_phdr

(See also dlinfo(3), which obtains info about a dynamically loaded object)

Symbol Interposition and Library Load Order

6-15 §6.3

6 Symbol Interposition and Library Load Order	6-1
6.1 Symbol resolution and symbol interposition	6-3
6.2 Symbol resolution and library load order	6-9
6.3 Link-map lists (namespaces)	6-14
6.4 The global look-up scope	6-16
6.5 LD_DEBUG: tracing the dynamic linker	6-18
6.6 Exercises	6-24

The global look-up scope

- In most cases, symbol resolution is performed via an ordered search of objects listed in the global look-up scope (GLS)
- GLS is a list of following objects (in this order)
 - The main program
 - All dependencies of main, loaded in breadth-first order
 - Libraries opened with dlopen(RTLD_GLOBAL)
- Order of objects in GLS is similar to link-map list order
 - (There can be some differences when *dlopen()* is used)
- In some cases, symbol look-ups may search additional scopes
 - E.g., "local" scope and "self" scope
 - See discussion of Look-up scopes (later)

Symbol Interposition and Library Load Order

6-17 §6.4

6 Symbol Interposition and Library Load Order	6-1
6.1 Symbol resolution and symbol interposition	6-3
6.2 Symbol resolution and library load order	6-9
6.3 Link-map lists (namespaces)	6-14
6.4 The global look-up scope	6-16
6.5 LD_DEBUG: tracing the dynamic linker	6-18
6.6 Exercises	6-24

The LD DEBUG environment variable

- LD DEBUG can be used to trace operation of dynamic linker
 - LD_DEBUG="value" prog
 - *value* is one or more words separate by space/comma/colon
 - Ignored (for security reasons) in privileged programs
 - To send trace output to file (instead of stderr), use LD DEBUG OUTPUT=path
 - To list LD DEBUG options, without executing program:

```
$ LD_DEBUG=help ./prog
Valid options for the LD_DEBUG environment variable are:
             display library search paths
 reloc
             display relocation processing
 files
             display progress for input file
             display symbol table processing
 symbols
             display information about symbol binding
 bindings
             display version dependencies
 versions
             display scope information
 scopes
             all previous options combined
 all
 statistics display relocation statistics
 unused
             determined unused DSOs
 help
             display this help message and exit
```

man7.org

Symbol Interposition and Library Load Order

6-19 §6.5

The LD_DEBUG environment variable

- libs: show locations where each library is searched for
- files: emit message as each library is opened
- reloc: emit message at start of relocation processing for each object
- symbols: for each symbol relocation, show which library symbol tables are searched
- bindings: for each symbol relocation, show object containing definition to which symbol binds
 - Corresponds to final entry shown by symbols (unless symbol is undefined)
- versions: display version dependency checks that are performed for each object
 - Relates to symbol-versioned libraries

The LD DEBUG environment variable

- All of the preceding LD_DEBUG values also cause DL to display messages when:
 - Each object's constructors and destructors are executed
 - On transfer of control to main()
- In addition, there are the following LD DEBUG values:
 - scopes: display search scopes for symbol relocation (objects) that will be searched during relocation for this object)
 - See the discussion of Look-up scopes (later)
 - unused: used to implement "ldd -u" (in conjunction with setting LD_TRACE_LOADED_OBJECTS=1)

Shared Libraries on Linux

©2025 M Kerrisk

Symbol Interposition and Library Load Order

6-21 §6.5

LD_DEBUG example

(Abridged) example of output from LD_DEBUG:

```
$ LD_DEBUG="reloc symbols bindings" ./prog
32150: relocation processing: ./prog
                  lookup in file=./prog [0]
32150:
        symbol=x;
        symbol=x; lookup in file=./libdemo.so.1 [0]
32150:
        binding file ./prog [0] to ./libdemo.so.1 [0]: normal symbol `x'
32150:
```

- "relocation processing" message from reloc
 - One message per library
- "symbol...lookup in file" messages from symbols
 - One group of messages for each symbol relocation
- "binding file...symbol" message from bindings
 - One message for each relocated symbol, showing origin of reference, object containing defn, and symbol name
- Number at start of each line is PID of process

man7.org

LD_DEBUG example

Another LD_DEBUG example:

```
$ LD_DEBUG=scopes date
21945:
21945: Initial object scopes
21945: object=date [0]
21945: scope 0: date /lib64/libc.so.6 /lib64/ld-linux-x86-64.so.2
...
```

- LD_DEBUG=scopes shows look-up scopes of each loaded object
- Here, we see the global look-up scope that is visible to the executable object, "date"

Symbol Interposition and Library Load Order

6-23 §6.5

6 Symbol Interposition and Library Load Order	6-1
6.1 Symbol resolution and symbol interposition	6-3
6.2 Symbol resolution and library load order	6-9
6.3 Link-map lists (namespaces)	6-14
6.4 The global look-up scope	6-16
6.5 LD_DEBUG: tracing the dynamic linker	6-18
6.6 Exercises	6-24

Exercises

The files in the directory shlibs/sym_res_load_order set up the scenario shown earlier under the heading Symbol resolution and library load order (slide 6-13). (You can inspect the source code used to build the various shared libraries to verify this.) The main program uses dl_iterate_phdr() to display the link-map order of the loaded shared objects.

① Use make(1) to build the shared libraries and the main program, and use the following command to run the program in order to verify the link-map order and also to see which versions of abc() and xyz() are called from inside libz1.so:

```
LD_LIBRARY_PATH=. ./main
```

Run the program using LD_DEBUG=libs and use the dynamic linker's. debug output to verify the order in which the shared libraries are loaded, and which locations are searched for each library.

```
$ LD_DEBUG=libs LD_LIBRARY_PATH=. ./main 2>&1 | less
```

[Exercise continues on the next slide]

Shared Libraries on Linux ©2025 M Kerrisk

Symbol Interposition and Library Load Order

6-25 §6.6

Exercises

Run the program and use the dynamic linker's debug output to show which libraries are searched and what definitions are finally bound for the calls to abc() and xyz().

```
$ LD_DEBUG="symbols bindings" LD_LIBRARY_PATH=. ./main 2>&1 | less
```

- The order in which the dependencies of main appear in the global look-up scope is determined by the order that the libraries are specified in the link command used to build main. Verify this as follows:
 - Modify the last target in the Makefile to rearrange the order in which the libraries are specified in the command that builds main to be: libz1.so liby1.so libx1.so
 - Remove the executable using make clean.
 - Rebuild the executable using make.
 - Run the executable again, and note the difference in symbol binding for the call to xyz() and the differences in the link-map order that is displayed by *dl_iterate_phdr()*.

man7.org
